Courteous but not curious: how doctors’ politeness masks their existential neglect. A qualitative study of video-recorded patient consultations

Kari Milch Agledahl,1 Pål Gulbrandsen,2,3 Reidun Førde,4 Åge Wifstad5

ABSTRACT
Objective To study how doctors care for their patients, both medically and as fellow humans, through observing their conduct in patient—doctor encounters.

Design Qualitative study in which 101 videotaped consultations were observed and analysed using a Grounded Theory approach, generating explanatory categories through a hermeneutical analysis of the taped consultations.

Setting A 500-bed general teaching hospital in Norway.

Participants 71 doctors working in clinical non-psychiatric departments and their patients.

Results The doctors were concerned about their patients’ health and how their medical knowledge could be of service. This medical focus often over-rode other important aspects of the consultations, especially existential elements. The doctors actively directed the focus away from their patients’ existential concerns onto medical facts and rarely addressed the personal aspects of a patient’s condition, treating them in a biomechanical manner. At the same time, however, the doctors attended to their patients with courteousness, displaying a polite and friendly attitude and emphasising the relationship between them.

Conclusions The study suggests that the main failing of patient—doctor encounters is not a lack of courteous manners, but the moral offensiveness patients experience when existential concerns are ignored. Improving doctors’ social and communication skills cannot resolve this moral problem, which appears to be intrinsically bound to modern medical practice. Acknowledging this moral offensiveness would, however, be the first step towards minimising the effects thereof.

INTRODUCTION
Caring for patients is a deep-rooted moral obligation in medicine, but what this means is unclear. Several empirical studies have shown that doctors rarely involve their patients in the clinical decisions made about them.1–4 Other research has highlighted how doctors focus on the technical and biomedical aspects of a case, and play down patients’ own values and feelings.5 6 In 2007–8, using observations and interviews, we studied how doctors handle the moral dimensions of their medical work.7 We found that doctors’ medical practice reflected the moral responsibility to improve patients’ health, while the personal and human dimensions of patients’ suffering were systematically left out. The account of “the good doctor” usually also implies practical human understanding and empathy and has deep roots in our culture, which shapes both patient expectations and doctors’ self-understanding.9

Patients and many doctors have welcomed the development of a more humanistic approach as a reaction to impersonal and scientific modern medicine.10 11 A renewed focus on the patient perspective and on how disease affects people’s lives has led to movements such as patient-centred medicine and shared decision-making,12–14 while also meaning that issues of ethics and communication, previously informal elements of a medical education, now are mandatory parts of the curricula in most Western medical schools.15

While a focus on patient autonomy and better communication has probably improved clinical encounters, it does not seem to have resolved the issue of professional caring. Lack of respect and empathy are among the most common complaints made by patients.16 17 The ongoing nature of these problems suggests that they are not just isolated cases of malpractice. They might indicate a systematic problem in medical care; however, we still have a long way to go to understand the dimensions of professional care involved in the patient—doctor relationship.

To consider this issue, we designed a new qualitative study using videotaped, routine consultations in a hospital. Our aim was to study how the doctors’ care for their patients was reflected in their conduct in order to shed light on what is involved in caring professionally for patients.

MATERIALS AND METHODS
We conducted a qualitative study on a representative sample of 380 videotaped encounters in a 500-bed general teaching hospital in Norway, which was a secondary analysis of an intervention study in 2007–8.18 The 71 doctors included in the study were randomly drawn from the population of doctors working in clinical non-psychiatric departments, and the encounters are a convenience-based sample of outpatient consultations, admittance and discharge consultations, ward rounds and consultations involving diagnostic procedures. The encounters were taped before, during and after the doctors had attended a course in clinical communication, and we excluded the recordings made after the intervention. We also excluded the minority of recordings that lasted more than 20 min because many of the longer consultations contained long periods of examination that were not visible on the tape and so were difficult to study.

The study group was constituted to include the broad expertise relevant to the research, with
Clinical ethics

a junior doctor and philosopher (KMA), a professor of philosophy (ÅW), an experienced general practitioner and professor of medical ethics (RF), and an experienced general practitioner and professor of health services research with expertise in clinical communication (PG). The first author watched randomly selected tapes from our subset and took notes on each encounter, focusing particularly on the doctors’ behaviour. The data were analysed for the purpose of generating explanatory categories in line with a Grounded Theory approach, and switching between periods of data observation and analysis was conducted hermeneutically to keep the theoretical concepts close to the data.19 20

The theory was developed in collaboration with ÅW, while RF and PG went through the data samples independently. After going through 101 encounters, new encounters did not disclose any significant new information, and saturation was achieved. In line with the methodology, KMA selected a subset of 12 encounters that each represented a main category in the emerging theory. All of the authors viewed the selected encounters together and agreed upon their interpretation. Of these, three typical consultations were selected, which illustrated the three main categories presented below particularly well. All authors agreed upon the final case descriptions and read and revised the manuscript.

RESULTS
We found that the doctors’ involvement with their patients could be classified according to three different dimensions: medical concern, courteousness and existential care.

The doctors’ medical concerns were mainly directed at how patients’ health was impaired and how their medical knowledge could help. This was evident from how they followed up patients’ complaints and how their time was prioritised and could be seen as part of the core contract between doctor and patient. Their strong sense of medical concern often caused the doctors to treat their patients as medical objects. Nevertheless, most related to their patients as more than mere objects, but the doctors interacted with their patients as human beings in a trivial manner. We have used the term courteousness to describe how the doctors often displayed a friendly attitude, kept a good tone and emphasised the social relationship with patients. By courteousness we refer to a display of general respect for the tone and emphasised the social relationship with patients. By courteousness we refer to a display of general respect for the social relationship with patients. The doctor overlooks the patient on medical facts from the records, which are read out loud. The doctor overlooks the patient’s own accounts of his life and he is declared healthy on the basis of a test result.

When the patient plucks up the courage to mention that his wife has died, the doctor ignores it. Instead of addressing this existential aspect, she quickly changes the subject with a medical concern: “Is there anything else you would like to ask?” “No!” he vigorously declares and rises to leave. The doctor leads him out and wishes him well.

The doctor’s first concern is to define the medical problem, and she focuses more on the computer than on the patient. She relies on medical facts from the records, which are read out loud. The doctor overlooks the patient’s own accounts of his life and he is declared healthy on the basis of a test result.

Nevertheless, they speak in a jovial manner. The doctor politely stands up to greet the patient and invites him to sit. She does not rush the consultation, answers the patient’s questions about lung function and exercise and takes time to explain matters in detail. Smiling and laughing, she appears to value the social contact. An ambiguous element to the expressed courteousness is revealed, however, when the doctor’s otherwise polite request for questions actually serves to interrupt the patient and bring an end to the consultation; a sign the patient seems to sense.

Case II: the anaesthesiologist’s round

An elderly woman sits in bed, glancing regularly at the door. “Mrs Peterson, is that you?” The doctor smiles, introduces himself as an anaesthesiologist and gets a chair. The patient asks whether he is going to carry out the sedation or the operation, but the doctor says no to both. In a friendly voice, he asks brief questions about her medical history, completing an anaesthesia form. The patient answers carefully. She is upset that her daughter had to take care of her because her current leg pain was not taken seriously. The doctor looks down, answering “yes” and “I see”. The woman’s phone rings and he waits for her to finish.

When the doctor starts to tell the patient about the epidural procedure, she looks uneasy. She asks repeatedly about medication and the possibility of a general anaesthetic. In a friendly voice, but hastily, the doctor explains the advantages of an epidural and proposes tranquillisers. The patient says she already has “so much tiny,
Case III: a cancer follow-up visit

A 60-year-old man enters with his wife. Diagnosed with metastasising cancer a year ago, he has undergone an operation and seven subsequent chemotherapy sessions. The doctor looks forthcoming and attentive and presents the medical history while glancing at the patient for confirmation. From the computer he identifies the current issue as the growth of one of the metastases. The patient explains that he can feel the tumour growing and the doctor asks about symptoms like urination problems, pain and nutrition. The patient describes a gradual loss of appetite, which he attributes to the weight loss. He also mentions that he feels physically weak and mentions that his wife comments on a lack of energy and that they have been to hospital several times for symptoms of anaemia. The doctor asks about symptoms like urination problems, pain and nutrition. The patient describes a gradual loss of appetite, which he attributes to the weight loss. He also mentions that he feels physically weak and mentions that his wife comments on a lack of energy and that they have been to hospital several times for symptoms of anaemia.

Left alone for a moment, the patient and his wife express anxiety at the rapid progress of the disease. In a timid voice, the wife asks about the possibility of improving the patient’s quality of life. The patient nods: “Yes, but I am afraid of surgery.” The doctor responds: “We can manage to radiate this one, I think.” The patient exclaims: “Yes! But this we can do with the sedation.” The doctor echoes: “Yes, I can see that...”

The patient looks anxious and asks about pain and if she will be awake during the surgery. The doctor reassures her in a friendly voice, but in a quick and impatient manner, and looks at the records: “Okay?” She hesitates: “Okay? I’m nervous. Terribly nervous. I am.” He promises her tranquillisers and repeats: “Okay?” She expresses insecurity about the surgeon and says the anaesthesiologist should be present. She laughs and stands: “Yes, I should. But I am unfortunately doing something else tomorrow.” He shakes her hand, wishes her good luck and leaves. The patient looks out the window. She sighs heavily.

The patient looks anxious from the beginning, and the doctor approaches her in a friendly and trustworthy way. He takes time to sit down, addresses her directly, looks straight at her and maintains reciprocal contact, demonstrating his courteousness. Seemingly encouraged, the patient eagerly answers his questions and shares her personal frustrations. After establishing this social contact, the doctor maintains a medical focus, framing his questions to deal with the anaesthesia form, taking no notice of the patient’s account of her distressing and humiliating experiences. When he has completed his medical tasks, he tries to end the consultation by almost compelling the patient to agree that everything is now “okay”, displaying again his delimited medical concern.

The doctor’s courteousness seems to be important to the patient, both as he patiently waits while she answers her phone and when they both start laughing. And yet, at this very moment, the doctor explicitly delimits his relationship with her and returns to his medical tasks. Although the doctor’s medical responsibilities may be limited to the anaesthetic procedure, existential care cannot be delimited as easily. Both the patient’s manner and her repeated questions about pain reveal her anxiety about the surgery. An attempt to deal only with the component of her fear that relates to an epidural procedure demonstrates an avoidance of her existential needs and is also ineffective. Only allowed to ask about the anaesthesia, the patient tries to frame her questions in terms of sedation, and ultimately states in general terms that she is ‘terribly nervous’. But the doctor never addresses the existential dimension of this fear and proposes the medical solution: more sedatives.

DISCUSSION

The study confirms our earlier findings: the doctors’ main focus was on medical problems, which overshadowed other aspects of the consultations, most notably the existential dimensions.17 Personal meanings of the patients’ conditions were systematically omitted or overlooked. Others have described doctors’ lack of empathetic responses and failure to respond to patients’ clues.21–23 The regularity of this conduct suggests that it should not be taken as an example of bad medical practice, but as part of the ordinary interactions between doctors and patients—that is, a function of ‘medical processing’.24 Bioethicists, as well as a major humanist movement in medicine, have called attention to the suffering of the patient, requested personal involvement of the doctor and emphasised the need to address patients as whole human beings with unique lifeworlds.25–27 Yet, in order to perform their clinical tasks, doctors must apply their scientific medical knowledge to their patients, which involves some objectification and a certain disregard for personal narratives; a suggestion advanced by medical sociologists decades ago.28 If it is inevitable that patients are treated as objects in order to help them medically, this might illuminate why the humanistic medical ideal has been so hard to achieve.

When doctors disregard patients’ personal accounts, they risk missing information that is clinically important, making the consultations less medically effective. In the second case, probing the elderly woman’s fear of surgery might have lessened her anxiety more than tranquillisers. But what is at stake here is
more than optimising patients’ medical treatment. By ignoring expressed existential matters, doctors disregard their patients’ humanity, which is a moral offence that is often perceived negatively. At the core of the conception of morality and human dignity is the idea that individuals are not reducible to objects, but intrinsically valuable. While most patients probably allow for this objectification, those with conditions that fundamentally affect their personal lives may be particularly vulnerable.

Although the study confirms doctors’ lack of personal curiosity and existential care, it also reveals that they are not insensitive to their patients as individuals. Indeed, the doctors in our study demonstrated a respect for their patients as fellow humans through social contact, polite behaviour and friendliness. Their strong medical focus often led the doctors to neglect personal accounts, but patients were also clearly treated with courtesy. While this ambiguity of professional care was exposed in many of the cases observed, there is little to suggest that the doctors were aware of it. Often, patients were handled in an almost mechanical manner, suggesting that the doctors conceived the circumstances as straightforward and uncomplicated. They shifted readily from talking cheerfully to patients, to reducing them to medical objects by letting the dialogue drift into a physical examination, or looking at the computer while making conversation. The doctors’ overt expressions of courteousness might actually conceal the ongoing objectification for both doctor and patient, leading the former to perceive the consultation as straightforward and satisfactory. When personal concerns were overlooked, the doctors’ friendliness often seemed to make their patients puzzled and unable to voice any protest.

When it comes to professional caring, the study reveals the importance of distinguishing between doctors’ existential care, which they mostly lack, and their courteousness, which they clearly display. Various attempts to foster professionalism among medical students and doctors have demanded empathy, altruism and integrity. However it is uncertain whether it is possible for doctors to care for patients existentially while also attending to their clinical responsibilities which requires them to apply a depersonalised medical science. Courteousness may improve the doctor—patient relationship, but the moral offence of being handled like a medical object cannot simply be undone by a friendly and polite doctor. Doctors should be familiar with the negative effects of their professional care even if they are unavoidable. When doctors are unable to follow up on a patient’s personal perspective, they should be aware of the moral harm caused by this rejection. They should seek to minimise it by attending to his/her humanity as far as possible within the medical setting, and apologise when unable to address personal issues. Courteousness can thus have moral significance if expressed, not to conceal an ongoing medical objectification, but to recognise the patients’ humanity, which is always threatened in a professional doctor—patient relationship.

Our qualitative findings cannot be generalised in the same way as quantitative results. The consultations were taped at one Norwegian hospital, and care should be taken in applying our findings to other fields. Medical practice in Norway is not fundamentally different from that in other Western countries, suggesting that the results are transferable to similar settings elsewhere. Our findings are also in accordance with similar studies from other countries, as highlighted in this discussion.

We had a large sample size and the participant doctors varied in specialty, age and experience. However, only hospital doctors were included, and it is possible that general practitioners attend more to the patients as people. The fact that the doctors knew that they participated in a study of clinical communication probably made them more conscious of their actions, not displaying their worst behaviour. In light of this bias, it is interesting that we still found such a lack of existential care.

Acknowledgements We would like to express our gratitude to the patients and doctors who kindly participated in the study, and to Bård Fossli Jensen, who did a major job in including patients and taping encounters. We would also thank the JME reviewers for helpful and constructive comments.

Funding KMA received funding from Finnmark Hospital Trust (NO) and Northern Norway Regional Health Authority. South-Eastern Norway Regional Health Authority funded the study in which data were collected. The funding sources had no role in the design, data collection, data analysis, data interpretation, writing, or decision to submit the article for publication.

Competing interests None.

Ethics approval This study was conducted with the approval of the REK Sør-Øst C, Postboks 1130, Blindern, 0318 Oslo, Norway (Nr 2009/913). All patients and doctors provided written informed consent.

Contributors PG was responsible for the study in which the videotapes were collected, and collected some of the videotapes. KMA and AW developed the theoretical framework and designed the study, KMA analysed and interpreted all data and wrote the first draft of the manuscript. AW, PG and RF participated in the data analysis and interpretation. All authors reviewed and revised drafts of the manuscript and had full access to all data in the study. All authors made a final approval of the version submitted for publication. KMA is the guarantor.

Provenance and peer review Not commissioned; externally peer reviewed.
