ABSTRACT
The COVID-19 pandemic has prompted unprecedented global disruption. For medical schools, this has manifested as examination and curricular restructuring as well as significant changes to clinical attachments. With the available evidence suggesting that medical students’ mental health status is already poorer than that of the general population, with academic stress being a chief predictor, such changes are likely to have a significant effect on these students. In addition, there is an assumption that these students are an available resource in terms of volunteerism during a crisis. This conjecture should be questioned; however, as those engaging in such work without sufficient preparation are susceptible to moral trauma and adverse health outcomes. This, in conjunction with the likelihood of future pandemics, highlights the need for ‘pandemic preparedness’ to be embedded in the medical curriculum.

INTRODUCTION
The COVID-19 outbreak has rapidly transitioned into a global pandemic. The implementation of social distancing, the closure of non-essential businesses and the limitation on travel have prompted a dramatic change in day-to-day functioning. Particular disruption is evident within the education sector with infection control policies mandating the closure of schools and universities. To facilitate the continued provision of education, major curricular and examination restructuring has taken place. While all those in higher education are subject to the consequences of such change, the particulars of medical education leave this cohort particularly susceptible. Medical education programmes are traditionally divided into two components: an initial university based preclinical phase and a subsequent clinical phase within the healthcare setting. This necessary duality is such that the curriculum is not readily compatible with the removal of students from their clinical attachments. Furthermore, a major response to the COVID-19 crisis has been a call for volunteers. Medical students, as future healthcare professionals, are perceived as being particularly likely to have a role in this regard. However, without appropriate ‘pandemic preparation’, these students are vulnerable to moral trauma and negative health outcomes. Yet, it is questionable whether such preparation has been established.

In a crisis, healthcare services that are at a point of extreme strain may unwittingly exploit the inherent altruism of many medical students. This, coupled with a lack of pandemic preparedness education in medical school, could leave these student volunteers vulnerable to unnecessary risk. This discussion explores the challenges faced by medical students during the COVID-19 pandemic, as well as the potential role of these students in a healthcare emergency.

MEDICAL EDUCATION AND COVID-19
The response by medical schools to COVID-19 has been varied. The closure of universities, public libraries and the limited access to alternative study spaces has forced many students into an unaccustomed learning environment. Rapid examination restructuring means that those who are preparing for or undertaking assessments must contend with new test formatting and marking structures in a short period. Some schools have delayed or advanced examinations, while some have decided to cancel them entirely and use previous summative and formative performance. For example, many universities have chosen to remove written assessments and replaced these with remote online assessments for students. Such an examination format raises legitimate concerns over the honesty and fairness of this process. Unsupervised online assessments rely on an individual’s integrity as the only safeguard against cheating. Various approaches have been considered as alternatives, including carrying these assessments as grade point neutral, mandating a passing grade only. However, although this balances the evaluation, it negates the time and effort spent by students to obtain a high mark—a grade that may contribute to their degree classification.

Moreover, the educational integrity of the medical programme is particularly vulnerable to the effects of COVID-19. An early focus on clinical teaching has been a central element of medical education reform in recent years. Academic programmes now adhere to a strict template: a shortened preclinical period where students are educated within the university and a subsequent clinical component during which students operate externally to their university and within the healthcare environment. This shift in pedagogy requires that preclinical students convene in groups for tutorials, problem-based learning, anatomy lab sessions and simulated patient interactions and that clinical students have access to patient care centres. Although lecture-based teaching is easily transitioned to an online format, interactive small group sessions and clinical exposure are not as easily replicated. Given this curricular structure, the COVID-19 pandemic has birthed a frustrating dichotomy for medical students. A virus that exploits human contact for survival is impeding an educational ecosystem that also necessitates human interaction.
Though the institutional response to COVID-19 has been rapid, with a commitment to the delivery of academic services with minimal disruption, such swift and unparalleled reorganisation is likely to be distressing for many students. The complexity of the challenges posed is exemplified by the unprecedented necessity of medical schools around the world to restructure their final year assessments, as well as calling on those students to enter the workforce months earlier than usual.9–14 These changes present both a logistical and personal challenge, particularly relevant for those transitioning from student to doctor, an evolution that has long been recognised as challenging.15–17 Available evidence suggests that medical students’ mental health status is already poorer than that of the general population,18 with academic stress being a chief predictor of ill health.19 Exposing final year medical students to an expedited graduation and placement at the frontline may exacerbate this and is already a concern expressed by some in the UK.19 Furthermore, medical students and graduates are recognised as an occupational group with a high prevalence of suicidal ideation and death by suicide.19 A recent meta-analysis suggested suicidal ideation to be even more prevalent in medical students than qualified doctors.20 Perceived work-related stress has been identified as being strongly correlated.21 There is no doubt that many students are ready to accept this challenge. However, for many, this is likely to be a daunting experience.

THE ROLE OF MEDICAL STUDENTS IN A CRISIS

During this pandemic, volunteering within the healthcare sector has been a cornerstone of the International response.22–24 However, due to extensive uncertainty and divergence about the appropriate roles for medical students during a pandemic, student participation in clinical care has varied across institutions.25 While some universities have prohibited any patient interaction, others have recruited students for hospital-based roles as either students or early graduated frontline workers.26,27 Although medical students may be assumed to be a natural reservoir of volunteers, this assumption deserves scrutiny.

A 2019 survey of medical students at the National University of Ireland, Galway, demonstrated that 59% of participants were willing to volunteer in the event of an infectious crisis. Most participants agreed that healthcare professionals have a moral obligation to volunteer in a pandemic with 81% believing that students should be encouraged similarly. Furthermore, of participants, 98% indicated altruism as a motivating factor for such volunteering.28 Given the severity of COVID-19, however, is altruism alone sufficient to warrant the deployment of learners? While these motivations are commendable, they cannot be allowed to replace adequate clinical competencies. As students cannot match the knowledge, skills and clinical experience of a qualified doctor, one might then contend that their involvement in the care of a patient with COVID-19 would primarily be for the students’ educational benefit, rather than for the provision of meaningful healthcare.29

A delicate balance exists between the risks and benefits of deploying medical students in emergencies—whether it is acknowledged or not. Though we are living through extraordinary times, care should be taken not to, perhaps conveniently, assume a level of preparedness on the part of medical students that belies their training at this juncture. During the academic programme, students are introduced to the healthcare setting in a controlled manner. Throughout their clinical attachments, they operate passively, shadowing teams, taking histories and observing procedures. Therefore, although this programme structure creates a stable learning environment, it does not ensure that students acquire the confidence and skills necessary to function appropriately during a pandemic. Gouda and colleagues found that only a minority of students (4%) believed that they were prepared in terms of their current skills and experience.28 These findings are recapitulated in other works that highlight that although the willingness to help persists, the lack of required knowledge and capability place these students, and patients, at risk in disaster situations.29–31 Moreover, in Belgium, a study posits that students are not fully aware of the implications of providing care during a pandemic and, as such, are not suitably informed to make a decision.32 Similar concerns are raised with the use of spontaneous volunteers in post-disaster situations by non-governmental voluntary organisations.33 With constrained services, and national pleas for volunteers, there is potential for students to be misguided in their choice. However, medical students, in the absence of requisite knowledge and preparation, introduce unnecessary risk for patients, other clinicians and themselves. Such students can act as vectors for viral transmission, consume personal protective equipment and place an additional burden on teaching physicians.34 Medical education alone does not justify these risks. However, facilitating medical students to participate in roles in which they have been prepared for may be of benefit.

PANDEMIC PREPAREDNESS

The findings that medical students are not fully aware of the implications associated with working during a pandemic highlights the need for the inclusion of pandemic/crisis specific content in the current curriculum. Medical students in the final years of their programme offer a vast wealth of potential. However, to effectively participate in the provision of healthcare and to function in a role that serves a higher purpose than just educational benefit, students must be prepared. A study on a disaster preparedness medical school elective in the USA showed that, of participants, 70% felt unprepared to participate in an emergency before commencing the elective. Subsequently, only 11% claimed to feel unprepared after training.34 Given the current thinking that further pandemics are likely,35 it befits medical educators to ensure that all prospective healthcare personnel are prepared. To date, however, few universities embed pandemic preparedness or disaster medicine training into undergraduate training. One study examining undergraduate disaster medicine education, found that fewer than 1 in 10 had ever heard about disaster medicine, standing in stark contrast to the overwhelming majority who welcomed such training (91%) and perceived it as being relevant to their future career (94%).35

Appropriate ‘pandemic preparedness’ involves a curriculum that assures academic competency, as well as education on the logistical challenges specific to pandemics. Approaches to the integration of these educational and logistical components have been varied.36 Such efforts include leadership courses in disaster response,37 problem-based learning for multidisciplinary preparedness,38 emergency preparedness exercises embedded in Public Health modules39 and an H1N1 vaccination drive-through aimed at introducing students to emergency preparedness issues.40

Additionally, suitable preparedness should involve an awareness of the tools and resources available for the maintenance of optimal student mental health. Not only are frontline staff placing themselves at physical risk, but the mental health sequelae of working during a pandemic have been documented.41 The rates of clinically significant distress affected a third to a half of
healthcare workers during the severe acute respiratory syndrome pandemic.43 Currently, the COVID-19 crisis is forcing healthcare professionals to make difficult decisions that might directly oppose their ethical and moral principles. Such choices include how to apportion inadequate resources to equally deserving patients, how to align their duty to patients with those to family and friends and how to provide care for all severely unwell patients with constrained or inadequate resources.44 Experiencing such an event may precipitate a ‘moral injury’. This term is used to conceptualise the psychological sequelae resulting from witnessing events that contravene personal beliefs,45 including feelings of guilt and shame due to an inability to have righted the wrongs committed. Moral injury has already been described in medical students, who report great difficulty coping when they were exposed to trauma that they felt unprepared for,46 potentially a mirror of the current predicament. In such unprecedented times, it is unreasonable to assume that medical students—with no training or experience—would be equipped to handle such responsibility.47

Mitigating the effects of such distress is vital for the prevention of adverse mental health outcomes. Therefore, appropriate pandemic preparedness should be structured as such. The development of resilience may offer a feasible intervention for incorporation into a university curriculum. This ability to mentally or emotionally cope with a crisis is an interplay between that person’s own capacity to manage their stress, as well as factors intrinsic to their workplace structure, such as effective leadership and access to support networks.48 Evidence suggests that preparation should be provided prior to a pandemic to build resilience.49 thereby reducing the impact of stress after exposure. Resilience training should focus on an individual’s confidence in being well-supported by their hospital/workplace, enhancing adaptive strategies of coping50 and building self-efficacy (one’s belief in their personal ability to respond adaptively to pandemic-related stresses).51 Furthermore, it should seek to reduce interpersonal problems, as such issues are associated with job stress in healthcare workers.52 In the case of medical students, such support needs to emanate from their universities and assigned clinical placements.

CONCLUSION

The educational restructuring necessitated by the spread of COVID-19, although disruptive for medical students, reflects a realisation that a paradigm shift in the traditions of medical education may be required. Pandemic preparedness seeks to ready students for action during a crisis. The benefits of such preparation will likely extend further, with strengthened resilience aiding in the transition from student to doctor. Although crises and the form in which they emerge cannot be predicted, it is a given that healthcare workers will be at the forefront of the response. Thus, the medical curriculum and its mode of delivery must reflect this. However, until such provisions are in place, no more should be expected of medical students than that of the general public.
